

CHAPTER 6: SCAN STRIKE & PROBABILITY

This is the final tier—where the analysis is translated into specific trading decisions. This layer is especially important for investors who use options.

6.1 Hiểu Delta trong Options

Delta	Practical significance
Delta 0.70–0.80	Deep ITM — stock-like options, low leverage, ~70-80% win probability
Delta 0.50 (ATM)	At The Money — equilibrium point, 50-50 probability
Delta 0.30–0.40	Slight OTM — a good balance between probability and profit
Delta 0.15–0.25	OTM — ~15-25% win probability, higher leverage
Delta < 0.15	Far OTM — lottery ticket, low win rate, often wasted

Golden rule: When selling options (short premium), choose a short strike with a Delta of 0.15–0.30 (~70-85% probability of running out of value). When buying options, choose a Delta ≥ 0.40 so that the options are not eaten up too quickly.

6.2 Probability of Profit (POP)

POP is the probability of a profitable position at maturity. This is the most important indicator to evaluate the quality of a transaction.

Probability criteria by strategy

Short Put / Cash Secured Put → POP > 70% (Strike dưới support quan trọng)

Bull Put Spread → POP > 65%, Risk/Reward tối thiểu 1:1

Iron Condor → POP > 60%, but small profit — used when IV% is high

Covered Call → POP > 75%, strike on the nearest resistance

Long Call/Put → No POP — use Risk/Reward $\geq 2:1$

6.3 Scan Strike theo Support & Valuation

Strike Price Selection Process:

5. Identify the technical support zone on the chart (weekly/daily)
6. Place the short put strike BELOW support by at least 5-10% — the "no touch" zone
7. Check the Delta of that strike: ideally a Delta of 0.20-0.30
